EMG monitoring system A muscle activity monitor, or EMG monitor, is a device used to assess muscle or nerve function. It is used in assessing and training people who have movement disorders. This is necessary for the individuals to determine their progress in treating these disorders. These studies are typically used in a clinical setting for inpatients. Components Instrument An EMG monitor consists of: Amp - An amplifier (magnetophone in the case of a surface EMG monitor), which allows the electrical signal generated by the electromyogram (EMG) electrode to be amplified. Filter - A band-pass filter, usually between 20 Hz and 400 Hz, which eliminates non-muscular electrical signals from the signal. The common frequency of current for a surface EMG monitor is 400 Hz. For a needle electrode, the frequency might be up to 100 kHz. Attachment - A device to which an EMG electrode is attached, typically to the patient's skin. Microphone - A microphone to pick up sound. In some cases, the microphone is embedded in the attachment. Display - A device that displays the amplitude and/or spectrum of the EMG signal. For example, a digital oscilloscope will show amplitude versus time, and a spectrum analyzer will show the spectrum of the signal as a function of frequency. Electrode An EMG electrode can be either a needle electrode or a surface electrode. The most common surface electrode is a bipolar electrode. A bipolar electrode consists of a pair of electrodes that is surrounded by a gel, the gel is designed to surround and encapsulate the electrode pair, and does not actually contact the muscle or nerve. A bipolar electrode is designed to detect muscle action potentials, which are the positive and negative peaks of the EMG. A surface electrode can be either a monopolar or a unipolar electrode. A monopolar electrode consists of one electrode, which is usually applied against the skin, and can be either a standard disposable Ag-AgCl electrode or a reusable Ag-AgCl electrode. A unipolar electrode consists of one electrode, which is usually applied against the skin, and is usually used with a pulse generator. This type of electrode is usually used with peripheral nerve stimulation. Monitor A surface EMG monitor usually has a display that shows the real-time signal, and the preceding waveforms, compared to a baseline

I have read the documentation but I still do not see the difference between KeywordExtension and WidgetExtension as prop types. const myproptype = ({mykeyword: value} as WidgetExtension) const myproptype = ({mykeyword: value} as KeywordExtension) I am getting the feeling I may be missing something. Will appreciate any help A: A good way to get a better understanding is to play with the different versions of the types. // A default object literal const foo = { a: 1 } as KeywordExtension // "a" is the Keyword property const foo = { a: 1, b: 2 } as WidgetExtension // "a" and "b" are the Widget properties // Explicit constructor type declarations class Bar extends React.Component { constructor(props) { super(props); this.state = { x: 1 }; } const bar = new Bar({
